## ABSTRACT

In recent work [1] it was shown how to rectify Gell-Mann's proposal for identifying the 48 quarks and leptons of the Standard Model with the 48 spin- $\frac{1}{2}$  fermions of maximal  $SO(8)$  gauged supergravity remaining after the removal of eight Goldstinos, by deforming the residual  $U(1)$  symmetry at the  $SU(3) \times U(1)$  stationary point of  $N = 8$  supergravity, so as to also achieve agreement of the electric charge assignments. In this Letter we show that the required deformation, while not in  $SU(8)$ , does belong to  $K(E_{10})$ , the 'maximal compact' subgroup of  $E_{10}$  which is a possible candidate symmetry underlying M theory. The incorporation of infinite-dimensional Kac–Moody symmetries of hyperbolic type, apparently unavoidable for the present scheme to work, opens up completely new perspectives on embedding Standard Model physics into a Planck scale theory of quantum gravity.

The question whether or not the maximally extended  $N = 8$  supergravity theory [2,3] can be related to Standard Model physics has been under debate for a long time. Very recent work [1] has taken up an old proposal of Gell-Mann's [4] on how to match the 48 quarks and leptons (including right-chiral neutrinos) of the Standard Model with the 48 spin- $\frac{1}{2}$  fermions of maximal  $SO(8)$  gauged supergravity that remain after the removal of eight Goldstinos (as required by the complete breaking of  $N = 8$  supersymmetry). This scheme, which was subsequently shown to be realised at the  $SU(3) \times U(1)$  stationary point of maximal gauged  $SO(8)$  supergravity [5], relies on identifying the residual  $SU(3)$  of supergravity with the diagonal subgroup of the colour group  $SU(3)_c$  and a new family symmetry  $SU(3)_f$ . Intriguingly, in this way complete agreement is found in the  $SU(3)$  charge assignments of quarks and leptons and the spin- $\frac{1}{2}$  fermions of  $N = 8$  supergravity, but there remained a systematic mismatch in the electric charges by a spurion charge of  $q = \pm \frac{1}{6}$ . The main advance reported in [1] was to identify the 'missing'  $U(1)_q$  that rectifies this mismatch, and that was found to take a surprisingly simple form. However, this deformation cannot be explained from 'within'  $N = 8$  supergravity (nor from a hypothetical embedding of maximal gauged supergravity into the known superstring theories), as  $U(1)_q$  is not contained in its R symmetry group  $SU(8)$ . In this Letter we show that the required deformation is, however, contained in an infinite-dimensional extension of  $SU(8)$ , namely the involutory 'maxi-

mal compact' subgroup  $K(E_{10})$  of the hyperbolic Kac–Moody group  $E_{10}$ , which has been proposed as a possible candidate symmetry of M theory [6].<sup>1</sup> This, we believe, places the question stated above, and also the eventual incorporation of the chiral electroweak gauge interactions (not considered in [4,5]), in an entirely new context, by embedding (at least a subset of) the Standard Model symmetries into an infinite-dimensional extension of the exceptional duality symmetries of maximal supergravity. This approach, never tried before to the best of our knowledge, offers completely new perspectives on the possible Planck scale origin of Standard Model physics.

For the rest of this text we will concentrate on the fermionic sector of  $N = 8$  supergravity, which consists of eight gravitinos  $\psi_\mu^i$  transforming in the **8**, and a tri-spinor of spin- $\frac{1}{2}$  fermions  $\chi^{ijk}$  transforming in the **56** of  $SU(8)$ , whence  $\chi^{ijk}$  is fully anti-symmetric in the  $SU(8)$  indices  $i, j, k$ , with (positive and negative) chirality corresponding to (upper and lower) position of the indices, and  $\chi^{ijk} = (\chi_{ijk})^*$ . Here we will, however, restrict attention to the vector-like  $SO(8)$  subgroup of  $SU(8)$ , for which the distinction between upper and lower indices is immaterial, whence we will not distinguish between  $\chi^{ijk}$  and  $\chi_{ijk}$  in the remainder. The residual vector-like  $SO(8)$  transformations act as

$$\chi^{ijk} \rightarrow U^i_l U^j_m U^k_n \chi^{lmn} \quad \text{with } U \in SO(8). \quad (1)$$

In order to obtain the correct electric charge assignments of the quarks and leptons it was found in [1] that the  $U(1)$  subgroup of  $SU(3) \times U(1)$  must be deformed by a new (still vector-like)  $U(1)_q$  whose action on the tri-spinor  $\chi^{ijk}$  is generated by the following 56-by-56 matrix

$$\mathcal{I} := \frac{1}{2} (T \wedge \mathbf{1} \wedge \mathbf{1} + \mathbf{1} \wedge T \wedge \mathbf{1} + \mathbf{1} \wedge \mathbf{1} \wedge T + T \wedge T \wedge T) \quad (2)$$

acting in the  $\mathbf{8} \wedge \mathbf{8} \wedge \mathbf{8}$  representation of  $SO(8)$ . Here

$$T = \begin{pmatrix} 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 \end{pmatrix}, \quad (3)$$

represents the imaginary unit in the breaking of  $SO(8)$  to  $SU(3) \times U(1)$ . We note that, from  $T^2 = -\mathbf{1}$  we have  $\mathcal{I}^2 = -\mathbf{1}$ , whence (2) can be trivially exponentiated to a  $U(1)_q$  phase rotation. The combination (2) differs from the usual co-product obtained from (1) with  $U = \exp(\omega T)$  by the 56-by-56 matrix  $T \wedge T \wedge T$ . Importantly, the latter is not in  $SU(8)$ , although it does commute with the  $SU(3) \times U(1)$  subgroup of  $SO(8)$ , and hence merely *deforms* this subgroup, but does not enlarge it. We will now show how to accommodate the triple wedge product  $T \wedge T \wedge T$  by enlarging the R symmetry  $SU(8)$  of  $N = 8$  supergravity to the bigger, and in fact, infinite-dimensional R symmetry  $K(E_{10})$ , in accordance with the anticipated enlargement of the finite-dimensional exceptional dualities of maximal supergravities to infinite-dimensional groups.

To proceed we recall how the fermions of  $D = 11$  supergravity [8] are related to those of  $N = 8$  supergravity [2,9]. Denoting the (spatial)  $D = 11$  gravitino components by  $\Psi_A^a$  (with  $a, b, \dots = 1, \dots, 10$  and  $D = 11$  spinor indices  $A, B, \dots = 1, \dots, 32$ ) and adopting the temporal supersymmetry gauge  $\Psi_A^0 = (\Gamma^0 \Gamma_a)_{AB} \Psi_B^a$  as in [10,11], we split the  $D = 11$  gravitino into four-dimensional spatial and internal components as follows

$$\Psi_A^a = (\Psi_{\alpha i}^{\hat{a}}, \Psi_{\alpha i}^{\bar{\hat{a}}}) \quad (4)$$

with flat spatial indices  $\hat{a}, \hat{b}, \dots = 1, 2, 3$  and flat internal indices  $\bar{a}, \bar{b}, \dots = 4, \dots, 10$ , whose position again does not matter as they are pulled up and down with  $\delta_{ab}$ . The  $D = 11$  spinor indices  $A, B, \dots$  are split as  $A \equiv (\alpha, i)$  into  $D = 4$  spinor indices  $\alpha, \beta, \dots = 1, \dots, 4$  and internal  $SO(8)$  indices  $i, j, \dots = 1, \dots, 8$  (whose position likewise does not matter here as we restrict attention to a vector-like symmetry). Ignoring a Weyl rescaling factor and a chiral redefinition, and not making a split into left-chiral and right-chiral components as in [9], we have

$$\psi_{\alpha\hat{a}}^i \propto \Psi_{\alpha\hat{a}}^i - \frac{1}{2} \sum_{\bar{c}=4}^{10} \Gamma_{ij}^{\bar{c}} (\gamma^5 \gamma_{\bar{a}} \Psi_{\bar{c}}^j)_{\alpha} \quad (5)$$

$$\chi_{\alpha}^{ijk} \propto \sum_{\bar{a}=4}^{10} \Gamma_{[ij}^{\bar{a}} \Psi_{k]\alpha}^{\bar{a}} \quad (6)$$

where we temporarily suspend the summation convention for the indices  $a, b, \dots$  (the summation convention remains, however, in force for all other indices). For the implementation of the action of  $T \wedge T \wedge T$  we also need the following redefinition of the  $D = 11$  gravitino [12]:

$$\Phi_A^{\bar{a}} = \Gamma_{AB}^{\bar{a}} \Psi_B^{\bar{a}} \quad (\text{no sum on } a!) \quad (7)$$

Because there is *no* summation on the spatial index  $a$ , manifest  $SO(10)$  covariance is lost. To emphasise this point we adopt a different font ( $\mathfrak{a}, \mathfrak{b}, \dots$ ) although these indices have the same range as  $a, b, \dots$  before [13]. Importantly, however, the position of the indices  $\mathfrak{a}, \mathfrak{b}, \dots$  now *does* matter, as they are to be raised and lowered with the (Lorentzian) DeWitt metric and its inverse

$$G_{\mathfrak{a}\mathfrak{b}} = \delta_{\mathfrak{a}\mathfrak{b}} - 1 \quad \Leftrightarrow \quad G^{\mathfrak{a}\mathfrak{b}} = \delta^{\mathfrak{a}\mathfrak{b}} - \frac{1}{9}. \quad (8)$$

With the redefinition (7) the formula (6) becomes

$$\chi_{ijk\alpha} \propto \sum_{\mathfrak{a}=4}^{10} \Gamma_{[ij}^{\mathfrak{a}} \Gamma_{kl]}^{\mathfrak{a}} \Phi_{\alpha}^{\mathfrak{a}}. \quad (9)$$

The action of  $T \wedge T \wedge T$  is therefore realised via (now suppressing  $D = 4$  spinor indices)

$$\begin{aligned} \chi_{ijk} &\rightarrow T_{il} T_{jm} T_{kn} \chi_{lmn} \\ &\propto \sum_{\mathfrak{a}=4}^{10} (T \Gamma^{\mathfrak{a}} T)_{[ij} (T \Gamma^{\mathfrak{a}} T)_{kl]} T_{lm} \Phi_{\mathfrak{m}}^{\mathfrak{a}} \end{aligned} \quad (10)$$

where we have inserted a factor  $TT = -\mathbf{1}$  and used the antisymmetry of  $T$ . Next we recall that there is a representation of the  $SO(7)$   $\Gamma$ -matrices where

$$T_{ij} = \Gamma_{ij}^{45} \quad (11)$$

(see e.g. Appendix E of [15]); it is then easy to see that

$$(T \Gamma^{\mathfrak{a}} T)_{[ij} (T \Gamma^{\mathfrak{a}} T)_{kl]} = \Gamma_{[ij}^{\mathfrak{a}} \Gamma_{kl]}^{\mathfrak{a}} \quad (12)$$

even without summation over  $\mathfrak{a}$ . Using this formula we conclude from (10) that the desired action takes a very simple form on the redefined spinors (7), to wit,

$$\Phi_{\alpha\mathfrak{a}}^{\bar{a}} \longrightarrow T_{ij} \Phi_{\alpha\mathfrak{a}}^{\bar{a}} \quad (13)$$

which leaves the  $D = 4$  spinor indices unaffected. Of course, one could also (though less elegantly) express this action in terms of the original spinors  $\Psi_A^a$ . We stress that in order to preserve the relation (5), (13) must hold for *all*  $\mathfrak{a} = 1, \dots, 10$ . From this follows the action of the new generator on the  $D = 4$  gravitino, an insight that the arguments in [1] could not provide. Observe that the redefinition  $\psi_{\hat{a}}^i \rightarrow \gamma^{\hat{a}} \psi_{\hat{a}}^i$  implied by (7) does not affect this conclusion, as  $\gamma^{\hat{a}}$  commutes with  $T$ .

We now want to show that the action (13) is contained in  $K(E_{10})$ , the supposed R symmetry of M theory. We refer to our previous work [10,11,13,14] for detailed explanations on  $K(E_{10})$ , and here simply summarise some salient results (see also [16,17] for related work). The group  $K(E_{10})$  is the involutory subgroup of  $E_{10}$  which is left invariant by the Cartan–Chevalley involution defined on  $E_{10}$  in terms of its Chevalley–Serre presentation. As such, it contains the R symmetries of all  $D \geq 2$  maximal supergravities as subgroups (and thus also *chiral* transformations for even  $D$ ); more specifically, we have

$$SU(8) \subset SO(16) \subset K(E_9) \subset K(E_{10}) \quad (14)$$

The fermions transform in spinorial (double-valued) representations of  $K(E_{10})$ . A remarkable property of the algebra  $K(E_{10})$  is that, though infinite-dimensional, it admits *finite-dimensional*, hence *unfaithful* representations [11,16]. These are the Dirac [17] and vector–spinor representations [11,16], which can be directly deduced from  $D = 11$  supergravity (in addition, two ‘higher spin’ realisations are known [13]). As a consequence,  $K(E_{10})$  is *not* simple, because it has nontrivial (finite codimension) ideals  $\mathcal{J}$  which

are associated with the unfaithful representations in the way explained in [11]. Accordingly, the quotient  $K(E_{10})/\mathcal{I}$  is a finite-dimensional group; more specifically, denoting the vector-spinor ideal by  $\mathcal{I}_{\text{vs}}$ , evidence was presented in [13] that  $K(E_{10})/\mathcal{I}_{\text{vs}} = \text{Spin}(288, 32)$ . The fact that the ‘compact’ subgroup  $K(E_{10}) \subset E_{10}$  in this way gives rise to a *non-compact* quotient group is another unusual feature of  $K(E_{10})$ .

A convenient realisation of the  $K(E_{10})$  Lie algebra generators in the vector-spinor representation was found in [13,14] (following earlier work on  $K(AE_3)$  in [12,18,19]). Like the generators of  $E_{10}$ , the generators  $k_\alpha^r$  of  $K(E_{10})$  can be labelled by  $E_{10}$  roots  $\alpha$  and the associated multiplicity index  $r$ , but such that [14]

$$k_\alpha^r = -k_{-\alpha}^r, \quad \text{for all } E_{10} \text{ roots } \alpha. \quad (15)$$

As shown in [13], for the vector spinor representation there is a concrete realisation of these generators in terms of 320-by-320 matrices. For all *real* roots  $\alpha$  of  $E_{10}$  (for which the multiplicity label  $r$  is not needed) we have

$$(k_\alpha)_{aA,bB} = \frac{1}{2} X_{ab}(\alpha) \tilde{\Gamma}(\alpha)_{AB} \quad (16)$$

where the symmetric matrix  $X_{ab}$  is given by

$$X_{ab}(\alpha) = -\frac{1}{2} \alpha_a \alpha_b + \frac{1}{4} G_{ab} \quad (\alpha \text{ real}) \quad (17)$$

in terms of the root components  $\alpha_a$  in the ‘wall basis’ used in [13]; indices  $a, b$  are raised and lowered by means of (8). As explained in [13] there is a map from the  $E_{10}$  root lattice into the  $SO(10)$  Clifford algebra that associates to each root  $\alpha$  of  $E_{10}$  a particular element  $\tilde{\Gamma}(\alpha) = -\tilde{\Gamma}(-\alpha)$  of the Clifford algebra; furthermore the matrices  $\tilde{\Gamma}(\alpha)$  are anti-symmetric for  $\alpha^2 \in 4\mathbb{Z} + 2$  and symmetric for  $\alpha^2 \in 4\mathbb{Z}$ . Because the  $SO(10)$  Clifford algebra is finite-dimensional, and because there are infinitely many real and imaginary roots of  $E_{10}$ , it follows that infinitely many  $E_{10}$  roots  $\alpha$  are mapped to the same element of the Clifford algebra.

To prove that (16) indeed generates the algebra  $K(E_{10})$ , one substitutes the ten simple roots of  $E_{10}$  into (16) and verifies the defining relations for  $K(E_{10})$  [13] (the latter characterise the involutory subalgebra in a manner analogous to the Chevalley–Serre presentation for general Kac–Moody algebras [20,21]). The Lie algebra  $K(E_{10})$  in the vector spinor representation is thus generated by taking commutators of the above real root generators in all possible ways. In this way one ‘reaches’ all imaginary root spaces with  $\alpha^2 \leq 0$ . However, due to the unfaithfulness of the representation the image of the root space elements consists of linear combinations of finitely many basis elements. The generating elements, and thus  $K(E_{10})$ , leave invariant the Lorentzian bilinear form

$$(V, W) \equiv G_{ab} V_A^a W_A^b \quad (\text{of signature } (288, 32)). \quad (18)$$

For general imaginary roots the formula (16) is no longer valid with (17). What is clear, however, is that all matrices  $k_\alpha^r$  generated in this way are antisymmetric under interchange of the index pairs  $(aA)$  and  $(bB)$ , that is,

$$(k_\alpha^r)_{aA,bB} = -(k_\alpha^r)_{bB,aA}, \quad (19)$$

and can thus be written as a linear combination of matrices of the form (16), with either  $X_{ab}$  symmetric in  $(ab)$  and  $\tilde{\Gamma}(\alpha)_{AB}$  anti-symmetric in  $[AB]$ , or antisymmetric in  $[ab]$  and symmetric in  $(AB)$ . Because all such matrices leave invariant the Lorentzian bilinear form (18) they all belong to the Lie algebra of  $\mathfrak{so}(288, 32)$  [13].

Although we do not have a general formula for arbitrary imaginary roots, explicit formulas do exist for null roots  $\delta$ , and for certain time-like roots  $\Lambda$  [14]. For null roots  $\delta$ , we have

$$(k_\delta^r)_{aA,bB} = \varepsilon_{[a}^r \delta_{b]} \tilde{\Gamma}(\delta)_{AB} \quad (20)$$

with eight transversal polarisation vectors  $\varepsilon^r$ . For time-like roots  $\Lambda$  with  $\Lambda^2 = 2 - 4n$  (for  $n \geq 0$ ), the corresponding  $k_\Lambda^r$  can be realised in the form (16) by choosing a decomposition  $\Lambda = \alpha + \beta$  with  $\alpha^2 = \beta^2 = 2$  and  $\alpha \cdot \beta = -(2n + 1)$ ; this gives

$$X_{ab}^{(\alpha)}(\Lambda) = -\frac{1}{2} \alpha_a \alpha_b - \frac{1}{2} \beta_a \beta_b - (2n + 1) \alpha_{(a} \beta_{b)} + \frac{1}{4} G_{ab} \quad (21)$$

Taking  $n = 1$  (that is,  $\Lambda^2 = -2$ ) as an example and letting the decomposition range over all pairs of real roots  $(\alpha, \beta)$  with  $\Lambda = \alpha + \beta$  one thus re-constructs the full root space, of dimension  $\text{mult}(\Lambda) = 44$ . For larger  $n$  the multiplicity of  $\Lambda$  increases rapidly,<sup>2</sup> and one can no longer exhaust the full root space with the  $X_{ab}^{(\alpha)}(\Lambda)$ .

Returning to our initial problem we note that

$$k_{aA,bB} = G_{ab} T_{AB} \equiv G_{ab} \delta_{\alpha\beta} T_{ij} \in \mathfrak{so}(288, 32) \quad (22)$$

whence this matrix can be generated by a linear combination of matrices obtained by multiple commutation of the basic  $K(E_{10})$  generators (because a linear combination may be required, we omit the root and multiplicity labels on  $k$ ). To see how one can arrive at the requisite linear combination we note that there are infinitely many roots  $\alpha$  (both real and imaginary) that satisfy  $\tilde{\Gamma}(\alpha) = T = \Gamma^{45}$ . The task of finding a  $K(E_{10})$  generator that implements  $T \wedge T \wedge T$  of (13) is then reduced to finding a combination of tensors  $X_{ab}$  that equals  $G_{ab}$ . We are not aware of a single root that achieves this but establishing the existence of a linear combination can be achieved as follows. In accordance with (21) one considers the set of all  $X_{ab}$  that can arise from the commutation of two real root generators  $X_{ab}(\alpha)$  and  $X_{cd}(\beta)$  (given as in (17)) such that  $\alpha + \beta = \Lambda$  is an imaginary root that satisfies  $\tilde{\Gamma}(\Lambda) = \Gamma^{45}$ . Similarly, one can perform the same analysis for odd multiples of  $\Lambda$  given by  $(2k + 1)\Lambda$  since then  $\tilde{\Gamma}((2k + 1)\Lambda) = \tilde{\Gamma}(\Lambda) = \Gamma^{45}$ . We have shown by an explicit computer analysis that one can find a linear combination of the generated  $X_{ab}((2k + 1)\Lambda)$  that equals  $G_{ab}$  and therefore the desired realisation of  $T \wedge T \wedge T$  on the spinors of  $D = 11$  supergravity within  $K(E_{10})$ . The generator just constructed only extends the R symmetry  $SU(8) \subset SO(3) \times SU(8) \subset K(E_{10})$  and thus leaves the spatial rotation  $SO(3)$  symmetry untouched.

The above argument demonstrates the existence of an element of  $K(E_{10})$  that acts according to (13), but the combination identified above does not necessarily have a simple algebraic interpretation. Because the spinors  $\phi_A^a$  form an unfaithful representation of  $K(E_{10})$  there are infinitely many elements that act in this way, and it is thus possible that an alternative realisation of  $T \wedge T \wedge T$  exists that has a simple physical origin. For the realisation found here one already has to go up to level  $\ell = 18$  in a level decomposition of  $K(E_{10})$  (that follows directly from the corresponding tables for  $E_{10}$  given in [22]); there is thus no easy way of reproducing this result by simple iteration of the low level  $K(E_{10})$  transformation rules given in [11]. The explicit realisation of the charge shifting  $U(1)_q$  generator above relies on the existence of time-like imaginary roots and their integer multiples, but there may be other possibilities, in particular, using only real roots. In any case, it does not appear possible to construct the requisite element without use of the ‘hyperbolic’ over-extended root of  $E_{10}$ , since the structure of the root system of the affine subalgebra  $\mathfrak{e}_9$  is too restricted. In

<sup>2</sup> For instance,  $\text{mult}(2\Lambda) = 2472$ ,  $\text{mult}(3\Lambda) = 425058$  and  $\text{mult}(4\Lambda) = 130593068$ .

this sense, the extension to the full *hyperbolic* Kac–Moody algebra and its involutory subalgebra could be essential for linking  $N = 8$  supergravity to the real world.

We note that the embedding of  $T \wedge T \wedge T$  into  $K(E_{10})$  in principle also allows for a realisation of this transformation on the bosonic fields of the spinning  $E_{10}/K(E_{10})$  model studied in [11], although the ambiguities related to the unfaithfulness of the fermionic realisation of  $K(E_{10})$  remain to be resolved. More precisely, while there are infinitely many combinations of  $K(E_{10})$  generators that act in the same way on the fermions, these will act differently on the bosonic coset variables on which  $K(E_{10})$  is realised faithfully. The bosonic variables can thus in principle be used to remove all ambiguities.

The results of [1] and this Letter represent a significant shift away from the standard paradigm of how to understand the possible emergence of the Standard Model fermions from a Planck scale unified theory, as for instance embodied in currently popular superstring inspired scenarios of low energy ( $N = 1$ ) supergravity. There one starts from a finite-dimensional *compact* Yang–Mills gauge group (such as  $E_6 \times E_8$ ), with the fermions transforming in a standard representation. This symmetry is assumed to be present as a *space–time–based symmetry* already at the Planck scale, and then assumed to be broken in a cascade of symmetry reductions as one descends to the electroweak scale. By contrast, the present scheme proceeds from an infinite-dimensional group that can be fully present as a symmetry only in a phase of the theory *prior to the emergence of classical space and time*, in accord with the proposal of [6], and *crucially relies on the infinite-dimensionality of this group* (and the associated Kac–Moody algebra).<sup>3</sup> We emphasise once again that  $K(E_{10})$  does possess chirality, offering new perspectives for the incorporation of chiral gauge symmetries, such that the electroweak sector of the Standard Model may eventually be understood in a way very different from currently prevailing views.

<sup>3</sup> A curious observation also concerns the discrete subgroups of  $K(E_{10})$ : The finite group  $PSL_2(7)$ , a maximal discrete subgroup of the family symmetry  $SU(3)_f$  which was recently invoked to explain the quark mass hierarchy [23] sits naturally in the Weyl group of  $E_7$ . The latter is contained in the Weyl group of  $E_{10}$ , and thus also inside  $K(E_{10})$ .
